We examine the interpretation of the light scalar meson nonet as tetraquark states using QCD sum rules. With the interpolating current for the tetraquark states composed of scalar diquark and scalar antidiquark, first, we construct the QCD sum rules by means of the operator product expansion up to the operators of dimension 8 and show that there is no evidence of the coupling of the tetraquark states to the light scalar meson nonet. In order to have a stable sum rule, we propose a “good” interpolating current for the tetraquarks based on chirality arguments which includes scalar and pseudoscalar diquark–antidiquarks with equal weights. In particular, for the lowest tetraquark σ -meson, we perform detail analysis of the QCD sum rule and obtain mass for the $\sigma(600)$ around 780 MeV.

§1. Introduction

It is well known that some properties of the light scalar meson nonet stimulated to interpret them as various tetraquark states.¹⁾ It is important to get a justification for such tetraquark states from QCD. First we study the light scalar meson nonet with quark content of the scalar diquark and the scalar antidiquark within the QCD sum rules. Since the correlator for the tetraquarks for the sum rules has higher energy dimension than that for ordinary baryons, the operator product expansion (OPE) must be considered up to higher operators than those for ordinary baryons. We include the operators in OPE up to dimension 8 with the factorization hypothesis. It is shown that the contributions from the dimension 8 condensates are unexpectedly large to become dominant in the sum rules. Moreover their negative contributions to the sum rule break down the physical meaning of the sum rule.

In order to find a good interpolating current for which the large contributions from the high dimension operators could be canceled out in the sum rules, we study the current based on the instanton model for the QCD vacuum for two flavors. Since the $\sigma(600)$ has vacuum quantum numbers, this current is expected to have a strong coupling to σ state. An additional advantage of using instanton originated current lies in the fact that there is cancelation of the high dimension operator contributions in the OPE in the self dual fields.²⁾ With this inspection, we propose a “good” interpolating current for $\sigma(600)$. We show that this current has very peculiar chirality structure and leads to the cancelation of large high dimension operator contributions and some dangerous instanton contributions in the sum rules. With the OPE up to operators of dimension 10, we fit the mass of $\sigma(600)$ by applying the two resonance approximation to the phenomenological side of the sum rule in order to avoid the well-known problem of strong dependence of results on the value of the threshold for multi-quark systems.³⁾

§2. QCD sum rules for the light scalar mesons with scalar diquarks

In the picture of the tetraquark states, the light scalar meson nonet is generated by the diquark in the $\bar{\mathbf{3}}_f$ and the antidiquark in the $\mathbf{3}_f$, where the subscript f stands for flavor. Accepting the argument from the constituent quark model that two quarks in the scalar channel feel the strongest attraction by the perturbative one-gluon exchange⁴⁾ and the non-perturbative instanton dynamics,⁵⁾ the scalar diquark (antidiquark) should belong to $\bar{\mathbf{3}}_c$ ($\mathbf{3}_c$) in color space and to spin-zero state by Fermi statistic. From this structure, the interpolating current for the scalar nonet can be written as

$$J_S = N_S \epsilon_{abc} \epsilon_{ade} (q_{1b}^T \Gamma q_{2c}) (\bar{q}_{3d} \bar{\Gamma} \bar{q}_{4e}^T), \quad (2.1)$$

where $\Gamma = C\gamma_5$ and $\bar{\Gamma} = \gamma^0 \Gamma^\dagger \gamma^0$. Here N_S is the normalization constant, the indices a, b, c, \dots denote color, and the subscripts 1, 2, 3, 4 are introduced for flavor (See Ref.⁶⁾ for more details).

Within the narrow one resonance approximation in the phenomenological part of the sum rule, the Borel transform yields the following QCD sum rules up to the operators of energy dimension 8 for the scalar meson nonet :

$$\begin{aligned} C_0^S \mathcal{O}_0 M^{10} E_4(M) + C_{4,i}^S \mathcal{O}_{4,i} M^6 E_{2,i}(M) + C_{6,i}^S \mathcal{O}_{6,i} M^4 E_{1,i}(M) \\ + C_{8,i}^S \mathcal{O}_{8,i} M^2 E_{0,i}(M) = 2f_S^2 m_S^8 e^{-m_S^2/M^2}, \end{aligned} \quad (2.2)$$

where M is the Borel mass. The decay constant and the mass of the mesons of the scalar nonet are defined by $\langle 0 | J_S | S \rangle = \sqrt{2} f_S m_S^4$. The first index in the coefficients $C_{d,i}$ denotes the dimension in power of energy of the associated operators $\mathcal{O}_{d,i}$. Explicit forms of the sum rules are given in Ref.⁶⁾ As shown in Fig. 1 for $\sigma(600)$, the negative contributions from the operators $\langle \bar{q}q \rangle \langle \bar{q}i g \sigma \cdot Gq \rangle$ where $q = u, d, s$ in the dimension 8 operators dominate in the sum rule and make the left hand side (LHS) of the sum rule to become negative definite. The same situation happens in the sum rules for other members in the nonet. Moreover if we include the contributions from the direct instantons, we have a worse situation. This means that the QCD sum rules with the tetraquark interpolating currents consisting of the scalar diquark and the scalar antidiquark cannot be used to derive the properties of the light scalar meson nonet.

Fig. 1. LHS of the QCD sum rule for the $\sigma(600)$ using the scalar diquark–antidiquark interpolating current.

§3. QCD sum rule for $\sigma(600)$ with a current based on the instanton picture for the QCD vacuum

Generally, there are two possibilities in getting the color singlet from a system consisting of the diquark and the antidiquark. One is that the diquark belongs to $\bar{\mathbf{3}}_c$ and the antidiquark to $\mathbf{3}_c$. Another is that the diquark belongs to $\mathbf{6}_c$ and the antidiquark to $\bar{\mathbf{6}}_c$. These two possibilities inform us that there are five types of diquarks : scalar(S), pseudoscalar(P), vector(V), axial vector(A), and tensor(T). Therefore, in general, the interpolating current for the light scalar mesons may have the form

$$J_S = \alpha J_S^{S\bar{S}} + \beta J_S^{P\bar{P}} + \gamma J_S^{T\bar{T}} + \omega J_S^{V\bar{V}} + \eta J_S^{A\bar{A}}, \quad (3.1)$$

where $J_S^{i\bar{i}}$ means the current consisting of the appropriate type of diquark (i) and antidiquark (\bar{i}). To fix the coefficients, we will use the instanton induced diquark antidiquark vertices which can be obtained from the famous t'Hooft instanton induced quarks interaction for the two flavor case⁷⁾ :

$$\mathcal{L} = \frac{G}{4(N_c^2 - 1)} \left[\frac{2N_c - 1}{2N_c} \left((\bar{\psi}\tau_\mu^- \psi)^2 + (\bar{\psi}\gamma_5\tau_\mu^- \psi)^2 \right) + \frac{1}{4N_c} (\bar{\psi}\sigma_{\rho\sigma}\tau_\mu^- \psi)^2 \right]. \quad (3.2)$$

By using the Fierz transform, we can rewrite the Lagrangian in terms of the diquarks

$$\begin{aligned} \mathcal{L} = & \frac{G}{2N_c(N_c - 1)} \epsilon_{abc}\epsilon_{ade} \left((u_b^T \Gamma_S d_c)(\bar{u}_d \bar{\Gamma}_S \bar{d}_e^T) - (u_b^T \Gamma_{PS} d_c)(\bar{u}_d \bar{\Gamma}_{PS} \bar{d}_e^T) \right) \\ & + \frac{G}{4N_c(N_c + 1)} (u_a^T \Gamma_{T,\rho\sigma} d_{a'}) \left((\bar{u}_a \bar{\Gamma}_T^{\rho\sigma} \bar{d}_{a'}^T) + (\bar{u}_{a'} \bar{\Gamma}_T^{\rho\sigma} \bar{d}_a^T) \right), \end{aligned} \quad (3.3)$$

where the spin matrices are given by $\Gamma_S = C\gamma^5$, $\Gamma_{PS} = C$, $\Gamma_{T,\rho\sigma} = C\sigma_{\rho\sigma}$ and $\bar{\Gamma}_i = \gamma^0 \Gamma_i^\dagger \gamma^0$. One can see that only three diquarks, scalar, pseudoscalar, and tensor diquarks can strongly couple with the instanton. From the above Lagrangian, for $N_c = 3$, it is expected that the interpolating current with the coefficients, $\alpha : \beta : \gamma = 1 : -1 : 1/4$, $\omega = \eta = 0$, may provide some specific properties to the OPE for the $\sigma(600)$. Indeed, if we restrict our consideration only to the current of the scalar and the pseudoscalar diquark-antidiquarks, we can immediately recognize that the equal weights ($\alpha^2 = \beta^2$) between the two types of the diquarks give a special chirality structure to the interpolating current :

$$\begin{aligned} \alpha J_\sigma^{S\bar{S}} + \beta J_\sigma^{P\bar{P}} \sim & -(\alpha - \beta)(u_L^T C d_L \bar{u}_L C \bar{d}_L^T + u_R^T C d_R \bar{u}_R C \bar{d}_R^T) \\ & + (\alpha + \beta)(u_R^T C d_R \bar{u}_L C \bar{d}_L^T + u_L^T C d_L \bar{u}_R C \bar{d}_R^T), \end{aligned} \quad (3.4)$$

where we have dropped the color indices for simplicity. From this chirality structure, one can easily see that the contributions from the operators associated with two chirality flips to the OPE should have the numerical factor of $\alpha^2 - \beta^2$. Therefore, the dimension 8 operators, which gave the dominant contributions to the previous sum rules with the scalar diquark-antidiquark only, will disappear in the sum rule for the currents with the equal weights of the scalar and pseudoscalar diquark-antidiquarks, $\alpha = \pm\beta$. The same cancelation happens in the contributions from

other high dimension operators and from the direct instantons associated with the two chirality flips. Besides, the spin structure of the tensor current restricts the OPE contributions from the high dimension operators. As a result, one can expect stability in the sum rule with such an interpolating current. By applying the two resonance approximation to the phenomenological part of the sum rule to avoid the well-known problem of the strong dependence of the multiquark mass on the value of the threshold of the continuum,³⁾ we get the mass of $\sigma(600)$ around 780 MeV with the value of the threshold, $s_0 = 2.0$ GeV.⁸⁾ However, the numerical factor $\alpha^2 - \beta^2$ appearing in the contributions from the high dimension operators and from direct instantons may give indication on the existence of two good interpolating currents for σ -state with $\alpha = \beta$ and $\alpha = -\beta$. We have shown recently that the contribution arising from the two pion intermediate state favors the tetraquark current with $\alpha = \beta$.⁹⁾

§4. Conclusions

We have shown that the interpolating current consisting of the scalar diquark–antidiquark and the pseudoscalar diquark–antidiquark for the tetraquarks have very peculiar chirality structure. It has been demonstrated that the chirality structure of the current with equal weights between the scalar and the pseudoscalar diquark–antidiquarks leads to a vanishing dangerous contributions from direct instantons as well as from the high dimension operators in the OPE. As a result, we obtain the stable QCD sum rule and the mass of $\sigma(600)$ around 780 MeV.
